

Can Economic Opportunities Reshape Gender Norms among Religious Youth? Evidence from Northern Nigeria

Benjamin Crost Oeindrila Dube Marcus Holmlund
Eric Mvukiyehe Emily Crawford*

October 2024

Abstract

Can extending economic opportunities to marginalized youth promote female empowerment and alter gender norms? We answer this question in the context of Northern Nigeria, a region where many women are disempowered by restrictive religious gender norms. Through a randomized control trial, we extend vocational training to impoverished youth, who reside in contexts shaped heavily by a very conservative interpretation of Islam. Our study population includes boys residing in Koranic boarding schools as well as girls receiving an Islamic education. The program we study trains youth in specific trades but does not directly target gender attitudes in any way. Our results show that vocational training substantially increases income-generating activities and earnings for beneficiaries. Moreover, it transforms beneficiary views around gender, leading to more equitable perspectives on whether women should be allowed to attain schooling, work, and have a say in household finances. Importantly, this transformation emerges not just for program beneficiaries, but also their parents and caregivers, who play a critical role in determining whether female wards work, and therefore, in shaping the future economic trajectories of women in the region. Our results highlight the critical role economic opportunities can play in engendering social change.

We are grateful to our partners in the UK's FCDO, in particular to Ed Smithson, Richard Sandall, Chris Price, Ogechukwu Omeribe, Tonia Momodu, Kristen Hopkins, Conor Doyle, and Federica Di Battista. We would also like to express our deep gratitude to the entire Mafita project implementation team, including the former project directors Umar Mohammed, Ana Vinambres and Erling Petersen, and to the broader team at Adam Smith International including Alison Bell and Alex Elphinstone, for their collaboration. We would also like to thank Rachel Glennerster, Madeline McKelway, Sendhil Mullainathan, Emily Nix and Cyrus Samii for insightful comments; as well as participants at the 2021 APSA Annual Meeting and the UC San Diego development seminar for helpful suggestions on earlier versions of the paper. We also thank Aanchal Bagga, Rongmon Deka, Samih Ferrah, Nausheen Khan, Ijeoma David Ukoko and Nuruddeen Umar for critical research assistance and field coordination activities. The study was funded by FCDO Nigeria under the World Bank-administered i2i Trust Fund.

1. Introduction

Gender inequality is a pervasive challenge throughout the world, particularly in developing countries (Duflo, 2012; Jayachandran, 2015). Compared to men, women have lower levels of employment, income, health, education and decision-making power, and experience higher levels of violence. These gender gaps have been remarkably persistent, despite sustained efforts to reduce them. Cultural norms have played a key role in maintaining this inequity (Alesina et al., 2013; Fernández and Fogli, 2009; Fernández, 2013; Bertrand et al., 2015; Bursztyn et al., 2020). For instance, norms that restrict women’s personal autonomy and economic opportunities are widespread in many developing countries (Deininger et al., 2013; Bursztyn et al., 2023; Abou Daher et al., 2023).

In this paper we examine if expanding economic opportunities available to male and female adolescents can help to re-shape inequitable gender norms. Through a field experiment, we study the effects of extending vocational training to youth residing in two states of Northern Nigeria, both currently under Sharia law. In the region, religious beliefs and institutions favor a conservative interpretation of Islam; and prevailing gender norms limit female autonomy in making decisions related to the labor market. For example, the custom of *kulle* prohibits married women from interacting with non-family members of the opposite sex, restricting women’s mobility outside the home (Robson, 2000; Zakaria, 2001; Adeyemi et al., 2016); and fathers typically have the final word on the labor market participation of their unmarried daughters (Csapo, 1981; Erulkar and Bello, 2007; Para-Mallam, 2010; Laouan, 2018; Seff et al., 2022).

The vocational training program we study provides 9 months of trade-specific training. The training takes place in well-equipped workshops and is delivered by teachers who are highly skilled in the trade. Critically, the curriculum does not discuss promoting gender equity or changing gender norms.

Rather, the program aimed to extend economic opportunities to highly impoverished youth, in some of the most religiously conservative segments of Nigerian society. Our sample includes 1,824 youth from the most socio-economically disadvantaged groups in the country, including boys residing in free Quranic schools under the care of Mallams and girls receiving an Islamic education; along with orphans and disabled youth residing in charitable institutions. 900 of these youth were randomized to receive the training, while another 924 served as the control group.

To gauge the economic and social effects of these training opportunities, we measured economic and gender-related outcomes approximately 12 months after the adolescents completed the training. We uncover four sets of results. First, we find that the vocational training substantially improved the economic outcomes of participants, boosting an index of income and employment by .24 standard deviation units (SDs), and an asset index by .18 SDs. Second, we observe that the training also led to similar-sized improvements in gender norms. Trained adolescents displayed .12 SD larger increases in an index of gender norms, compared to those in the control group. For example, trainees were more likely to indicate that women should have a say in decisions related to household lending and borrowing, as well as having children. They were also more likely to support the idea that boys should do as much domestic work as girls, and that girls are as capable as boys in school. The fact that the training did not mention gender or have any gender related objectives limits the concern that these responses reflect social desirability bias, a challenge that the literature on gender and female empowerment generally has to contend with.

Disaggregating the analysis by gender reveals that the effect on girls' gender norms is larger and more precisely estimated. However, we cannot reject the hypothesis that the training affected male and female respondents equally (albeit potentially because we may lack the statistical power to detect small differences in effects across the two sub-samples).

We further find that the training led to a broadening of participants' social interactions.

Individuals exposed to the training have a higher percentage of friends who are employed, live outside the respondent's neighborhood, and are of the opposite gender as the respondent. To explore the relationship between gender norms, employment, and social interactions, we conduct a mediation analysis. This analysis suggests that employment is an important mediator of the training's effect on both social interactions and gender norms. These results are consistent with a mechanism in which trainees' increased employment led to a wider social network, which fostered a change in their gender norms.

Finally, and notably, we also observe that the training led to direct improvements in the gender attitudes of the caregivers of participants, which include parents and husbands. Exposure to the training changes an index of the caregivers' gender norms by 0.16 SDs. This effect is particularly strong for caregivers with a female ward enrolled in the study. Participants' caregivers were more likely to approve of female labor force participation. In addition, they were more likely to indicate that women should occupy leadership positions in society and have a say in decisions about their fertility. These changes in attitude are particularly important in the context of Northern Nigeria where caregivers make critical decisions in areas related to the marriage and employment of their female wards (Csapo, 1981; Erulkar and Bello, 2007; Para-Mallam, 2010; Laouan, 2018; Seff et al., 2022).

The findings in our paper contribute to two distinct literatures. We firstly contribute to the literature on the economic and social effects of job training. Previous research has yielded mixed results on the effectiveness of job training programs in developing countries. Early work in this literature found that vocational training had disappointingly small employment and wage effects (Card et al., 2011; Attanasio et al., 2011; Cho et al., 2013; Adoho et al., 2014; Blattman and Ralston, 2015; Hirshleifer et al., 2016). However, more recent studies have found more promising effects by showing that carefully designed training programs can have transformative effects on the lives of their participants (Attanasio et al., 2017; Alfonsi et al., 2020; Bandiera et al., 2020; Carranza and McKenzie, 2024). Our results complement these studies by showing that job training can generate substantial gains in income and em-

ployment even among a highly marginalized population with low labor market attachment in a fragile setting. While most studies in this literature have focused on the labor market effects of training, a small number of studies has also shown that vocational training programs can have wider social benefits, for example by reducing crime recidivism ([Newton et al., 2018](#)) and involvement with armed groups ([Blattman and Annan, 2016](#)). Our research adds another critical dimension to the positive social impacts of vocational training by demonstrating its effect on gender norms. These effects highlight the importance of considering broader social benefits in determining the overall effectiveness of job training.

Secondly, we contribute to the literature on gender norms in economics. Several recent experiments show evidence that efforts to re-shape gender norms explicitly can succeed in achieving this objective. This includes interventions that promote school-based discussions of gender equality ([Dhar et al., 2022](#)) and life skills training ([Edmonds et al., 2023](#)); as well as interventions that combine life skills and vocational training with safe spaces for girls ([Bandiera et al., 2020](#)).

Related work has demonstrated the success of economic incentives aimed at achieving ends like delaying early marriage ([Buchmann et al., 2023](#)); and shown that assisting women in finding jobs can serve to delay marriage and reduce fertility ([Jensen, 2012](#)). Gender empowerment has also been shown to emerge from levers that target cash transfers ([Almås et al., 2018](#)), assets ([Bandiera et al., 2017](#); [Bedoya et al., 2019](#); [Bossuroy et al., 2022](#)) and independent savings accounts for female beneficiaries ([Field et al., 2021](#)).¹

Our work builds on this literature in two ways. The training we evaluate does not set out to explicitly shift gender attitudes, or ameliorate gender inequity by solely promoting female work opportunities. Thus our results show how economic programs that do not target gender norms explicitly, or target women specifically, can also serve to re-shape gender attitudes. Moreover, we show these effects in the context of a society under Sharia law, thereby

¹Other gender effects of cash transfers have been shown by [Attanasio and Lechene \(2014\)](#), [Bobonis \(2009\)](#), and [Hasan \(2010\)](#)

building on a nascent literature that examines how gender attitudes can be changed in such settings, where gender norms are guided in by a strict interpretation of Islam. In this space, [Bursztyn et al. \(2020\)](#) examine how correcting mis-perceptions of social norms can achieve outcomes like increasing female labor force participation in Saudi Arabia. It is possible that training programs like the one we evaluate can shift gender attitudes in such a context by averting the potential negative signal that traditional gender empowerment programs might send in conservative societies ([Buchmann et al., 2023](#); [Ashraf et al., 2020](#)). Indeed, programs perceived to be at odds with traditional norms have the potential to generate backlash in such societies ([Glennerster et al., 2021](#); [Blumenstock et al., 2022](#); [Gazeaud et al., 2023](#)).

Third, we document that participant’s experience with skills training and improved labor market opportunities have the capacity to influence not only their own, but also their parent’s gender views. To our knowledge, this is the first paper to provide evidence for this kind of effect. This finding suggests a broader potential of interventions like this one to change gender norms, particularly in societies where guardians have the final word on female participation in the labor market and female labor supply decisions. Overall, our results are consistent with the existence of a virtuous cycle, in which interventions that improve women’s economic opportunities lead to a change in gender norms that in turn creates even more opportunities for women ([Duflo, 2012](#); [Jayachandran, 2021](#)).² Importantly, our findings point to a concrete policy lever that can be leveraged to kick-start this cycle.

2. Institutional Context

In this section, we provide background on poverty and gender norms in Northern Nigeria, two critical aspects of the region’s socioeconomic development which are integral to our study.

²Of course gender norms can also be altered through other conduits besides economic opportunities such as the influx of liberal gender norms from outside ([Jensen and Oster, 2009](#); [La Ferrara et al., 2012](#)). And, conversely, female economic outcomes can also be improved through other types of interventions besides those that target gender norms specifically ([Ashraf et al., 2020](#); [McKelway, 2018](#)).

Our evaluation takes place in the Northern Nigerian states of Kaduna and Katsina, which are both characterized by high levels of poverty. The percentage of people in extreme poverty, under 1 dollar per day (PPP adjusted), is 74% in Kaduna and 66% in Katsina ([Open Data for Africa, 2022](#)). Moreover, unemployment rates are above 25 percent in both states. These economic conditions underscore how extending economic opportunities to impoverished youth in the region could lead to substantial improvements in well-being.

Most of the population in both states is Muslim. The Nigerian Census has not collected data on religious affiliation since 1963, making it difficult to know the exact percentage of Muslim population by state. However, most estimates place the Muslim population at around 50% in Kaduna and above 95% in Katsina ([Ostien, 2018](#)). Muslims tend to come predominantly from the Hausa-Fulani ethnic group while most Christians are either Igbo or Yoruba. Both states adhere to a very conservative interpretation of Islam and have been under Sharia law since the early 2000s.

2.1. Gender Norms and Institutions in the Region's Religious Setting

Women in this context typically experience low levels of economic and social empowerment. Traditionally, women bear the brunt of domestic work and also exhibit low levels of employment outside the household ([Adeyemi et al., 2016](#); [Okojie, 1991](#); [Egbue, 2012](#); [Enfield, 2019](#)). One reason for these low levels of labor force participation is that young women tend to leave school early to marry and have children. In our experimental sample, at age 20, 41% of women are married, compared to only 1% of men. This lines up with previous estimates of marriage rates in rural Northern Nigeria at age 20 of about 50% of women and 4% of men ([Enfield, 2019](#)). Women also exhibit low levels of participation in civic activities such as politics or community leadership ([Egbue, 2012](#)).

The low levels of female empowerment in the region are strongly tied to religious beliefs and institutions that prescribe specific gender roles, based on a very conservative interpretation of Islam. One of the religious institutions limiting the economic empowerment of Muslim

women is the practice of seclusion, referred to either by the Hausa term *kulle* or the Arabic *pardah*. In its strictest interpretation, this practice prohibits women from interacting with non-family members of the opposite sex (Zakaria, 2001). Furthermore, married women are only allowed to leave their house occasionally, accompanied by their husbands (Adeyemi et al., 2016; Robson, 2000). While not all women are subject to this strict interpretation of *kulle*, many of them are restricted in their movement in some way by the practice. For instance, looser interpretations of *kulle* allow married women to leave their houses after dark, for essential visits to kin, or on other occasions with the permission of their husband (Adeyemi et al., 2016; Robson, 2000). Overall, however, these restrictions dramatically limit married women's ability to participate in the labor force and public life more broadly.

While the practice of *kulle* traditionally only applies to married women, unmarried women and adolescent girls also tend to have little decision-making authority. Fathers of unmarried women generally have the final, and often the only, say over decisions, including decisions about education, enrolment in training programs, labor market participation and marriage (Csapo, 1981; Erulkar and Bello, 2007; Para-Mallam, 2010; Laouan, 2018; Seff et al., 2022). For unmarried women whose father is deceased or otherwise unavailable, it is expected that a male relative or other man will step in and act as a guardian who will take these decisions for the young woman in his care.

Other religiously motivated norms limit women's decision-making power within the household. Many Muslim women are taught from childhood 'that God decreed that they should remain submissive to their husbands irrespective of their behaviours' (Callaway, 1986; Onwutuebe, 2013). This belief limits their ability to make choices about their fertility and resist intimate partner violence (Adeyemi et al., 2016; Enfield, 2019). Furthermore, inheritance and divorce laws under Sharia are heavily biased against women, further reducing their bargaining power and status within the household.

The restrictive gender norms of Northern Nigeria are reflected in the attitudes of our sample

population. In our sample, 87% of respondents in the control group said that men should be the sole decision-maker about large household purchases, and 76% said the husband alone should decide whether his wife is allowed to work outside the home. 48% of respondents say the husband alone should decide whether the couple has children. 49% said that it is more important to educate boys than girls, and only 48% said that girls should speak as much as boys in class.

These unequal gender attitudes are widespread even among girls, and among the portion of our study population not enrolled in Islamic education. For instance, 82% of girls not in Islamic education say that the husband should be the sole decision-maker for large household purchases, and 65% say the husband should decide the wife's place of work. Even among this group, 30% of respondents said that it is more important to educate boys than girls, and only 54% said that girls should speak as much as boys in class.

3. Overview of the Training Program

The vocational training program we study, called the Community Skills Development Centers (COSDEC) program, aimed to provide trade-specific training to impoverished youth. The training was implemented as a part of the Mafita skills-development program funded by the UK Foreign, Commonwealth, and Development Office (FCDO).

The first 3 months of the training consisted of classroom-based instruction in foundational skills (literacy, numeracy, and basic science), as well as “soft skills” training on topics like goal-setting and interpersonal communication.³ This was followed by approximately nine months of vocational training in one of six specific trades: Carpentry and Joinery, Electrical Installation, Fashion Design, Hospitality, Masonry, Office Management and Welding and Fabrication. This part of the training took place in fully equipped workshops under the supervision of teachers skilled in the trade. In addition to the core foundational and

³The soft skills component made up only a small part of the Mafita training - approximately 45 minutes a week, out of a total of 30 hours of training.

vocational training, some COSDEC participants were also offered an additional training in entrepreneurship and business administration that lasted for two months after the end of the vocational training.⁴

Since participants came from highly impoverished backgrounds, they were paid a stipend of 200 Naira per day (approximately \$0.67 USD) for 20 days of the month for the entire duration of their training. This stipend was intended to pay for food and transportation, so that the trainees could focus on their training and did not have to engage in other income-generating activities.

Mafita was designed with great care to be appropriate for local conditions. The curriculum was developed in collaboration with the National Board of Technical Education (NBTE), which oversees vocational education in Nigeria. At the end of their training, participants were encouraged to take the assessment exam and become certified in their trade. Approximately 73 percent of participants completed the program, and 70 percent of participants completed the program and obtained this certification.

To ensure a high quality of instruction, Mafita also worked with the COSDEC teachers to build their capacities and provide certification through a Master Training Program supervised by the NBTE. Regular classroom and workshop observations were conducted by senior staff to ensure that trainers followed the curriculum and adhered to the NBTE's guidelines for instruction.

Notably, the Mafita program had no gender component and did not target gender attitudes in any way. This program design decision was partly made to avoid backlash from local leaders against what could have been perceived as attempts to impose foreign cultural norms on the local population. For our study, the lack of gender component has the advantage of limiting the potential for social desirability bias among respondents. Since the training did not make

⁴In our analysis, we verify that the effects we observe do not depend critically on this component of the training.

gender issues salient, it is unlikely that social desirability would have led respondents who received the training to under-report conservative gender norms relative to respondents who did not receive the training.

4. Study Design and Methods

4.1. Sample Selection and Randomization Design

Eligibility for the COSDEC training was determined by age, income and membership in one of the marginalized groups targeted by the Mafita program. To be eligible, individuals had to be 15-24 years old and earn less than 226 naira per day (about USD 0.75 at the time of the study). In addition, they had to belong to one of the following marginalized groups: early school leavers, orphans and vulnerable children, persons with disabilities, boys in the “Almajiri” system ⁵, and girls in Islamiyyah/Quranic education, who are called “IQE” girls.

Since the latter two groups are somewhat specific to the Northern Nigeria context, we discuss them in greater detail here. The Almajiri are boys who have gone through the institution of Almajiranci, in which poor parents entrust male children to Islamic schools, to study with religious leaders called Mallams. This practice has a long tradition in Northern Nigeria, by some accounts dating back to the 11th century. In the present day, Almajiri tend to have little formal (secular) education and high rates of unemployment. They are largely stigmatized by mainstream society and often perceived to be delinquents and troublemakers.

Girls who receive a religious education receive it in Islamiyyah schools, which focus on Arabic studies and Qur’anic education. In many cases, the Islamiyyah schools do not replace secular schooling, and many girls attend both types of schools. In contrast to the male Almajiri, girls in Islamiyyah schools tend to live at home with their families.

The Mafita program targeted these later two groups based on widespread concerns that the

⁵This includes boys who are currently in an Almajiri school and those who have passed through the Almajiri system.

skills imparted by the Almajiri and IQE education systems have low returns in the labor market, in the hopes that COSDEC training could expand their labor market opportunities.

To identify eligible individuals, the Mafita project worked with a variety of intake sources that included state agencies such as the State Universal Basic Education Board (SUBEB), State Agency for Mass Education (SAME), as well as a variety of non-governmental organizations (NGOs). Mafita consultants visited intake sources, such as Islamic schools and NGOs that work with marginalized youth, and conducted data collection to ensure that the potential participants met the eligibility criteria.

During the outreach and screening effort, Mafita generated applications from 1824 eligible individuals who applied to their local COSDEC center. Prior to randomization, individuals applied to one of six centers where the trainings were conducted, specifying in advance the trade they wanted to be trained in. Out of the 1824 eligible applicants, 900 were randomly selected to receive the training, the other 924 were assigned to the control group. In the randomization, applicants were stratified at the center-trade level since each center had only a limited number of slots available in each trade. Applicants randomized into the training group were trained from April 2017 to March 2018. And, applicants randomized into the control group were not allowed to apply to a different trade or center for the duration of the study.

4.2. Data collection and measurement

Data collection for the endline survey commenced in December 2018 and was completed in May 2019. We developed the survey instrument in collaboration with the program implementers, and refined it through several rounds of pilot testing and field testing. Before data collection began, we developed a pre-analysis plan that specified which outcomes we would measure, as well as the exact survey questions that would be used to measure them. We put particular care into designing the survey instrument to measure the gender norms of youth and their caregivers, two key outcomes of interest for this study. Critically, we measure

the gender norms of caregivers, to gauge if having a female ward participate in the training alters their gendered perspective. We do this through an extensive array of questions administered to the participants' primary caregivers, most of which are their parents, husbands or Mallams. Like all other pre-specified outcomes, gender norms are measured as an index that aggregates answers to survey questions following the method of [Kling et al. \(2007\)](#).

The survey module on youth gender norms asked an extensive set of questions that covered three broad topics: household decision-making, women's equality and role in society, and domestic violence. In Section 6 below, we report results for the entire index that aggregates 28 questions on gender norms, as well as for sub-indices that separately aggregate the questions for each of the four topics. Control group means and estimated effects of the training on all questions in the gender norms index are reported in Appendix Table A1.

The questions on household decision making asked respondents which spouse in a married couple should be the main decision-maker in a particular household decision, such as making household purchases, lending money, the wife's place of work, etc. The possible answers are the husband alone, the wife alone, or that the decision should be made jointly. To calculate the index, we assign the value 1 if the respondent thinks the decision should be made by the husband alone, and zero if they think the decision should be made jointly or by the wife alone.

Some of the household decisions we asked about, such as household purchases and lending/borrowing money, are from standard modules (e.g. the DHS: [ICF, 2004-2017](#)), while others were adapted to capture the gender norms specific to the local context. For instance, we added questions about whether the wife should work outside the household, her working hours, and her participation in groups, all of which may reflect adherence to the religiously motivated practice of seclusion (*pardah/kulle*).

The questions on domestic violence ask whether a certain behavior by a wife would justify her husband beating her. Examples of behaviors are: if she goes out without telling him,

refuses to cook, neglects the children, etc. As in the household decision-making module, some of these questions are standard in modules of this kind while others were designed to reflect the local context (e.g., going out without telling the husband may reflect a violation of seclusion).

The questions about women's equality and role in society were designed to reflect broader norms not directly tied to specific decisions or behaviors. Examples include questions about whether women should occupy leadership positions in society, women should be allowed to work outside the home, and educating girls is as important as educating boys. Some of these questions were previously used by other studies, such as the World Values Survey ([Haerpfer et al., 2020](#)), and we developed others for the local context.

The caregiver gender norms outcome is an index that covers three topics: household decision-making, women's equality and role in society, and women's labor force participation. The first two topics are based on the same survey questions as the respective topics of the youth gender norms index. The questions about female labor force participation ask whether women of different ages and different marital status should work inside or outside of the household. For instance, we asked whether it is acceptable that an 18 year old married woman works outside of the household, whether a 22 year old single woman works at home, etc. The questions cover combinations of ages 14, 18 and 22, married and unmarried status, and working inside and outside the home. As for the youth gender norms outcome, we report results for the entire index that aggregates 30 questions on gender norms, as well as for sub-indices that separately aggregate the questions for each of the topics.

Prior to the start of the training, the Mafita program conducted its own baseline survey on a subset of program participants, as well as on other eligible youth who eventually were not enrolled in the study. This data was collected between October and December 2016 prior to the commencement of the training. Baseline data is available for approximately 85 percent of the study participants. We use data on some variables collected through the baseline

survey as additional controls in robustness tests reported in Section 6.

5. Empirical Strategy

We estimate the effect of the COSDEC training with the following equation:

$$Y_{is} = \beta_0 + \beta_1 T_{is} + X_{is}\Gamma + \alpha_s + \varepsilon_{is} \quad (1)$$

In this equation, Y_{is} denotes the outcome of interest for individual i in randomization strata s . The variable T_{is} is an indicator for being randomly assigned to receive the training, and X_{is} is a vector of pre-specified control variables collected at intake before the randomization was carried out. The equation also includes a set of strata fixed effects, α_s . As described in Section 4.1, randomization was stratified at the training-center-by-trade level. As discussed there, participants chose which trade and which center to apply to. We then randomly assigned 30 applicants in each center-trade cell to receive training (this is because there were exactly 30 training slots available for each trade in each center). By controlling for strata fixed effects, we account for the fact that the probability of being randomized into the treatment group was higher for the less popular trade-center combinations. By including these fixed effects, our analysis compares youth who applied for the same trade in the same center, some of whom were randomly chosen to receive training and others to serve as control.

Compliance with the randomization was high – the training was completed by 73 percent of individuals in the treatment group. A small fraction of individuals in the control group (approximately 7 percent) was able to participate in the training. However, the coefficient β_1 reflects the intent-to-treat effect (ITT) of being randomly assigned to the training group. Estimates of the effect of randomization on training completion are reported in Appendix Table A2, which are large and statistically significant.⁶

⁶The table also shows that the training had little effect on literacy, which we pre-defined as a measurable outcome of training success. This is most likely because literacy was only covered in the initial three months

Our pre-analysis plan specified 7 primary outcomes, all of which are measured by mean effects indices following [Kling et al. \(2007\)](#).⁷ For these outcomes, we report hypothesis tests that adjust for multiple hypothesis testing by controlling the False Discovery Rate (FDR), as well as sharpened q-values for the FDR following [Anderson \(2008\)](#).⁸

Our analysis of the gender norms index deviates from the pre-analysis plan in two ways. First, the pre-analysis plan specified that we would only estimate the effect of training on the gender norms of female study participants. Later, we decided to expand this analysis to include male participants as well, to test the hypothesis that observing their female peers' success in the training and labor market could affect their gender norms.⁹ Our decision to expand the sample for this analysis to male participants necessitated a second deviation: we restricted the gender norms index to only include survey items that reflect norms about women's role in society, even when they are reported by a male respondent. Specifically, the originally specified version included a section on the respondent's experience of domestic violence, their desired age of marriage and fertility, and a measure of their confidence in their own cognitive ability.¹⁰ These survey items can be interpreted as a measure of gender norms when reported by female respondents, but not necessarily when reported by male respondents. For example, a female respondent's desired age of fertility partly reflects her norms about when women should have children and how much control they should have over their reproduction. However, a male respondent's desired age of fertility is less relevant to our research question because men's reproductive behavior is less constrained by cultural norms, and because we are specifically interested in norms about women's role in society.

of foundational skills training, and even there made up only one component of foundational skills, which also included numeracy and basic science.

⁷The pre-analysis plan can be accessed at <https://www.socialscisearch.org/trials/4637>.

⁸This approach was pre-specified in the pre-analysis plan, which divided outcomes into primary and secondary. The primary outcomes reflect the main hypotheses we set out to test with this study. We anticipated that the secondary outcomes would be part of the exploratory analysis and pre-specified that we would not adjust for multiple hypothesis testing across them, in order to preserve the statistical power of the primary hypothesis tests. The effect of the training on all pre-specified outcomes, both primary and secondary, is reported in Appendix Table A3.

⁹Note that this deviation is only relevant to the gender norms index – we pre-specified all other analyses to be conducted on the full sample of study participants.

¹⁰We measured this confidence by eliciting the respondent's belief about how they would perform on a "Raven's matrix" cognitive test.

We therefore exclude these items when calculating the gender norms index. However, in the appendix we report the originally pre-specified analysis that uses all pre-specified measures of gender norms and restricts the analysis to the female sub-sample and we find similar results.

Appendix Table A4 reports tests for balance on observable characteristics across the treatment and control groups. The results of these tests show that the groups are balanced on a wide range of characteristics, both from the pre-randomization intake interview and the baseline survey conducted by the implementing NGO.

Appendix Table A5 shows tests for selective attrition. Attrition was low overall at approximately 6 percent of the sample, reflecting a high response rate for a marginalized population with high rates of migration. However, attrition was slightly more frequent in the control group than the treatment group, most likely reflecting the treatment group's higher incentive to stay close to the training center, which may have outweighed other incentives to migrate (the estimated difference in attrition rates is approximately 3 percent). The imbalance in attrition rates across the treatment and control groups was particularly high in the two centers in Southern Kaduna (Kagoro and Mando), shown in Appendix Table A6. This region experienced a flare-up of violent conflict between herders and farmers that began in 2016 and lasted well into the second half of 2017.¹¹ This conflict led to substantial internal displacement in the region and likely increased people's incentive for outward migration (Ibrahim et al., 2022). The results in Appendix Table A7 show that in the other four centers not located in Southern Kaduna, attrition is balanced across the treatment and control group. A robustness test, reported in Appendix Table A8, shows that excluding the two centers in Southern Kaduna does not substantially change the estimated effects of training.

Appendix Table A4 also shows that the remaining sample of non-attriters is balanced on the relevant characteristics, so the imbalance created by the attrition process is unlikely to

¹¹<https://www.chathamhouse.org/2017/02/violence-southern-kaduna-threatens-undermine-nigerias-democratic-stability>.

have a large effect on our estimates. Appendix Table [A5](#) shows that there is imbalance in some characteristics between attriters and non-attriters, for example gender and Almajiri status. However, due to the low overall attrition rate, the remaining sample of non-attriters is still strongly balanced on all variables. In the appendix we also verify that our estimates are not affected by controlling for an extended set of observed characteristics that include the variables that were unbalanced across attriters from the treatment and control groups (see Appendix Table [A22](#)). To quantify the possible extent of bias from selective attrition, Appendix Table [A9](#) reports Lee bounds, which do not include zero for any of our main outcomes of interest.

6. Results

Table [1](#) reports estimated effects of the training on economic outcomes and gender norms. All outcomes in this table are mean effects indices calculated following [Kling et al. \(2007\)](#). The outcomes shown in the top panel were specified as primary outcomes in the pre-analysis plan, and we adjust their hypothesis tests for multiple hypothesis testing. The table shows that the training had a substantial effect on economic outcomes, increasing the income and employment index by 0.24 standard deviations and the asset index by 0.18 standard deviations.

Estimates of the training's effect on the components of the income and employment index are reported in Appendix Table [A10](#). These estimates indicate the training's effects were large compared to the control mean. For instance, individuals exposed to the training experienced a 40 percent increase in wage employment relative to the control mean, and a 54 percent increase in wage income. The bottom panel of the table also shows that the training also had a large positive effect on assets and expenditures, increasing the index for this outcome by 0.18 standard deviations. Estimates of the training's effect on the components of the asset and expenditure index can be found in Appendix Table [A11](#). This table shows that the training led to substantial increases in expenditures in almost all measured categories,

including food, cell phone minutes, clothes, medical expenses, and leisure. It also led to increased ownership of cell phones, generator sets, and bank accounts. In addition, we observe a modest increase in job search behavior, increasing the associated index by 0.08 standard deviations. Overall, our estimates suggest that the COSDEC training had a transformative impact on the lives of its participants, leading to a dramatic expansion of their economic opportunities.

In Appendix Table [A12](#), we show how training affected subjective well-being and self-esteem. The well-being index is composed of a five-question mental health screening tool (MHI-5) and a measure of life-satisfaction (Cantril's ladder).¹² The self-esteem index is composed of seven questions that measure the respondents feelings of self-worth and control over their life. Appendix Table [A12](#) shows that though the training did not affect self-esteem, it led to an increase in well-being. This effect is driven by a large increase in the Cantril's ladder item, which suggests that access to the training made participants more satisfied with their life as a whole.

Effects on Youth Gender Norms

Table [1](#) also shows that the training had a substantial effect on gender norms, increasing the youth gender norms index by 0.12 standard deviations and the caregiver gender norms index by 0.16 standard deviations. Table [2](#) further explores these effects by reporting separate estimates for the components of the gender norm indices. In that table, we group together individual questions into components on household decision-making, women's role in society and domestic violence to assess which aspects of gender norms change in response to the training training. However, in Appendix Table [A1](#), we additionally present effects on all underlying variables that make up this index. When we instead consider the pre-specified measures of gender norms that apply only to women (see discussion in Section [5](#)), we observe the same effect. These results are reported in Appendix Table [A13](#).

¹²Cantril's ladder asks: "Please imagine a ladder with steps numbered from zero at the bottom to 10 at the top. The top of the ladder represents the best possible life for you and the bottom of the ladder represents the worst possible life for you. Which step are you currently on?"

Table 2 shows that the training had important effects on youth's norms about household decision-making and women's role in society, increasing the corresponding component indices by 0.12 and 0.10 standard deviations. As shown in Appendix Table A1, the impacts on household decision making are driven by changes in views around whether women should have a say in their decisions to have children, and the household's lending and borrowing decisions. Only 50 percent of individuals who did not receive training believe that women should have a say in the decision to have children. Exposure to the training increased this measure by 4.3 percentage points (a 9 percent increase above the control mean). Only 26 percent of individuals who did not receive training agreed that women should have a say in the household's decision to borrow money (30 percent for lending money). Exposure to the training increased this measure by 5.7 percentage points (5.8 for lending), an increase of over 20 percent of the baseline mean. Exposure to training also reshaped respondents' norms about whether boys should do as much domestic work as girls, whether girls are as capable as boys in school, and whether girls should speak as much as boys in the classroom. For instance, only 30 percent of individuals who did not receive training believe that boys should do as much domestic work as girls, and exposure to the training increased this measure by almost 9 percentage points, or almost 30 percent of the baseline mean.

In contrast, the training had little effect on norms around domestic violence against women – the estimate in Table 2 demonstrates that effects on this component index are small and statistically insignificant (as are the effects on the underlying variables in Appendix Table A1). This pattern of results suggests that exposure to the training, which is delivered in a school setting and provides participants with labor market opportunities, changes norms about related contexts such as education and financial decisions more than norms about other contexts such as intra-household violence.

While it is in principle possible that our estimates results suffer from social desirability bias, there are two reasons why we believe that this is not a major concern. First, the enumerators were locally recruited and therefore come from the same cultural background

as the respondents, where conservative gender norms are widespread. It is therefore unlikely that respondents feel the need to hide conservative gender norms. This is reflected in our survey data, as discussed in Section 2.1: 87% of respondents in the control group said that men should be the sole decision-maker about large household purchases, and 76% said the husband alone should decide whether his wife is allowed to work outside the home. 48% of respondents say the husband alone should decide whether the couple has children. 49% said that it is more important to educate boys than girls, and only 48% said that girls should speak as much as boys in class. Second, the training had no explicit gender component, so gender issues would not have been any more salient to individuals who received training than to those who did not. It is therefore unlikely that social desirability would have led respondents who received the training to under-report conservative gender norms relative to respondents who did not receive the training.

Table 3 explores heterogeneous impacts by gender of the participants. For female participants, training led to a statistically significant increase in the gender norms index of approximately 0.14 standard deviations. The effect on male participants is slightly smaller at 0.8 standard deviations, and not statistically significant. However, additional analysis shows that the difference in estimated effects between male and female participants is not statistically significant. Thus, we cannot reject the hypothesis that the training affected male and female respondents equally, albeit this could partly be because we lack the statistical power to detect small differences in effects across the two sub-samples.

Effect on Caregiver Gender Norms

We next turn to estimating the training's effect on the norms of participants' caregivers. Caregivers may change their gender norms either as a direct result of their wards' changed gender norms, or by observing their ward's positive experience with the training and their resulting improved labor market outcomes. They may also experience that people with religious authority, such as the Mallams, are less opposed to women's participation in training and the labor market than they previously assumed, which could lead to a change in gender

norms through a mechanism similar to the one documented by [Bursztyn et al. \(2020\)](#).

One difficulty in estimating this effect arises from the fact that some caregivers have multiple wards enrolled in the training, so that they cannot be assigned to a unique stratum fixed effect (e.g. if the two wards applied to different trades). In our baseline specification, we address this by restricting the sample to caregivers with a single ward in the study. For this subsample, we can estimate the effect of training with equation 1, the same equation we used to estimate the effect for the participating youth. Results of this estimation are presented in Table 4. In Appendix Table A14, we also show results for the entire sample, using an estimating equation that allows a caregiver to have multiple strata fixed effects – one for every strata in which they have a participating ward. These estimates are very similar to the ones from our baseline approach in Table 4.

The results in Table 4 show that, as for youth, the training had a substantial effect on caregiver's norms about the role of women in society, increasing the corresponding component index by 0.16 standard deviations. In addition, the training had a large effect on caregiver's norms about female work decisions, increasing the component index by 0.12 standard deviations. We report the effect of training on all variables that make up the index in Appendix Table A15. Appendix Table A16 disaggregates the caregiver effect based on the gender of their ward. We observe that the effect is strongest for caregivers with female wards in the study. This is consistent with a mechanism in which directly observing a female ward's success in the training and subsequently the labor market leads to a change in the caregiver's gender norms. By contrast, the effect on caregivers with only male wards in the study is small and not statistically significant.

The impact on caregiver norms is particularly important because of the considerable influence caregivers have on the work decisions of their female wards. As discussed above in Section 2, young women in Northern Nigeria generally have little autonomy over their work decisions, usually needing the permission of their husband, parents or other caregivers to

seek employment. Many observers attribute the very low female labor force participation in Northern Nigeria to religious norms these caregivers hold against women working outside of the household (Egwurube, 2016; Enfield, 2019). By softening these norms, the COSDEC training could have substantial positive impacts on young women's ability to join the labor force. As shown in Appendix Table A15, changes in the caregiver's gender norms reflect changes in views around whether women should occupy leadership positions in society and, as in the case of youth gender norms, whether boys should do as much domestic work as girls and speak as much as boys in the classroom. These effects, combined with the observed impact on questions related to female work decisions, reinforces the idea that the training alters gender norms pertaining to educational and economic opportunities.

Effect on Social Networks

Table 5 shows that the training had large positive effects on several outcomes related to participants' social networks. In particular, participants experienced a significant increase in the number of employed friends, friends of the opposite gender, and friends who live outside the neighborhood. It is likely that this broadening of social interactions is at least partly explained by the increase in labor market opportunities of trained individuals. Participants who found employment may have gained friends among coworkers and perhaps through interactions with customers and bosses, and most of these new friends would likely be employed. Even participants who did not find employment themselves likely formed social ties with others who did, and thus became connected to a new social network. This mechanism may also explain the increased number of friends outside of the neighborhood. Many participants lived in poor neighborhoods where employment opportunities are rare and thus found jobs outside of their neighborhood, exposing them to wider social networks there.

Overall, our results suggest that the training led to a broadening of participants' social networks, which may have affected their gender norms. Before the training, study participants were part of relatively parochial social networks in poorer, more religiously conservative neighborhoods. A broadening of these networks likely exposed them to new perspectives

on many social issues, including gender norms. The hypothesis that this broadening of social interactions affected participant's gender norms is consistent with previous evidence that interactions with Muslims from other countries led to a change in gender norms among participants in the Haj ([Clingsmith et al., 2009](#)).

Appendix Table [A17](#) explores whether the integration into broader social networks described above led to a loss of connections with the participants' old social networks. We find no evidence for this. The training has no effect on trust in the respondent's family, people in the respondent's own neighborhood or people the respondent knows personally. It also has no negative effect on participants' time spent with family or probability of borrowing money from friends and family. Furthermore, it has no effect on the probability that the respondent currently lives or studies with a Mallam, which suggests that program participants were not excluded from their old religious networks. On the contrary, the training had positive effects on the respondent's confidence in religious leaders of their own religion and on the number of friends in religious school. In addition, individuals who received training were more likely to participate in youth groups and sports clubs. Overall, these results suggest that the broadening of social networks described above did not come at the cost of weakening existing social ties.

While social networks appear to have broadened along dimensions related to the labor market, we see more mixed evidence on network expansion along dimensions of religiosity. As can be seen in Appendix Table [A18](#), people do not report more friendships from those of other religions. They do report greater trust of people and leaders from other religions, but there is also no effect on decisions to donate to charities from another religion (the Red Cross for Muslims and the Red Crescent for Christians).

In addition, in this table, we observe a decrease in an index of religiosity, but the largest and most precise effects in the index stem from Mafita participants spending less time on religious activities and an increase in the belief that other things are more important than

religion, respectively. This is consistent with Mafita participants working more, and potentially attaching relatively greater value to work. More generally, this result points to the opportunity cost of time playing a role in religious engagement. Finally, Appendix Table [A19](#) shows that the training had no additional downstream effects on religious enforcement or anti-social behavior.¹³

Overall, these results suggest that the training caused a substantial expansion in participants' social networks along dimensions related to employment, gender and geographic reach, while not significantly reducing their existing social ties.

Mediation analysis: the role of labor market outcomes

To what extent did improvements in trainees' labor market outcomes play a role in bringing about the observed changes in their gender norms and social networks? To explore this, Table [6](#) shows the results of a mediation analysis that follows [Heller et al. \(2017\)](#). Column 1 shows the experimentally estimated effects of the training on the potential mediator: the income and employment index. This is the same estimate shown in Table [1](#), which shows that the training increased income and employment by 0.24 standard deviations.

Column 2 shows the correlation between the income and employment index (the potential mediator) and the two outcomes of interest, gender norms and social networks, in the control group. The results show that the income and employment index is strongly correlated with both outcomes. Individuals in the control group who score higher on this index also have broader social networks and more equitable gender norms. While this correlation is not experimentally estimated, it is consistent with the hypothesis that employment leads to a broadening of social networks and a change in gender norms away from the conservative religious norms many study participants are exposed to.

¹³As described in the pre-analysis plan, religious enforcement was partly measured through a series of vignettes that asked respondents whether they would take action to punish violations of religious norms like blasphemy, drinking alcohol, wearing a miniskirt.

Column 3 reports the share of the total effect of training on the respective outcome that could be explained by the training's effect on income and employment. This estimate comes from multiplying the effect of the training on the income and employment index reported in column 1 by the (non-experimentally estimated) link between the index and the respective outcome in column 2, and then dividing by the effect of the training on the outcome. Following [Heller et al. \(2017\)](#), we obtain confidence intervals by bootstrapping with 5000 bootstrap replications.

The results in column 3 show that the effect of the training on income and employment could explain close to 20 percent of its effect on both gender norms and social networks. While these results utilize non-experimental variation, and should therefore be interpreted somewhat cautiously, they do provide suggestive evidence that the increase in trained individuals' labor market opportunities played a meaningful role in broadening their social network and changing their gender norms.

Robustness tests

We conducted several additional robustness tests, which we report in Appendix Tables [A20](#) and [A21](#). These tables report results of regressions that exclude participants in the additional entrepreneurship training. As discussed in Section 6 above, this additional training was offered non-randomly to 352 individuals in the treatment group – approximately 41 percent of the group, and 19 individuals in the control group. We therefore cannot estimate its effect separately from the effect of the vocational training component of the COSDEC program. However, the estimates in Appendix Table [A20](#) show that the precision and magnitude of all our key outcomes remain unchanged, which indicates that the effects are not driven by the additional entrepreneurship training and instead reflect the program's core vocational training component.

Appendix Tables [A22](#) and [A23](#) show results from regressions that control for additional variables from the baseline survey. The estimates from these regressions are similar to

those of our baseline specifications. Appendix Table [A24](#) shows estimates using inverse-covariance weighted versions of the outcome indices, following [Anderson \(2008\)](#), which are very similar to our baseline estimates with unweighted indices following [Kling et al. \(2007\)](#). Appendix Table [A13](#) shows results for the originally pre-specified index of gender norms of female participants, which includes desired age of marriage and fertility and confidence in cognitive abilities. Again, the results are very similar to those from our preferred specification in [Table 2](#).

7. Conclusion

This paper provides evidence of the transformative potential of economic interventions in re-shaping gender norms in the context of a religiously conservative society. Our evidence comes from a randomized controlled trial of the Mafita program in Northern Nigeria, which extended vocational training to youth from economically disadvantaged and religious backgrounds, including boys residing in Quranic boarding schools and girls receiving an Islamic education. Our findings reveal several significant insights.

First, vocational training led to substantial improvements in the economic well-being of participants, who had higher incomes and higher rates of employment a year after the training. This shows that skills training can significantly improve livelihoods even among highly disadvantaged populations with low attachment to the labor market.

Second, though the curriculum did not discuss female empowerment or address gender inequity in any way, it had a pronounced impact on gender norms. Participants who received training exhibited more progressive gender attitudes, supporting women's participation in household decisions, endorsing shared domestic responsibilities between boys and girls, and acknowledging the capabilities of girls in education.

Furthermore, the impact of the training extended beyond the participants themselves. Caregivers and guardians of female participants also exhibited improved gender attitudes, par-

ticularly with regard to supporting female labor force participation and women's roles in leadership and decision-making. Given the influential role of caregivers in Northern Nigerian society, this could be highly consequential for furthering gender equality in the region. One implication of this finding is that avoiding an explicit focus on gender empowerment or targeting women specifically may help to successfully re-shape gender attitudes in culturally conservative societies.

Our mediation analysis also suggests that increased employment served as a key pathway through which the training influenced gender norms. This underscores the interplay between economic development and gender norms, and the role economic improvements can play in spurring positive changes in societal norms.

In conclusion, our evidence highlights the potential of skills training as a powerful tool for promoting gender equity and economic empowerment, offering a path towards a more inclusive and equitable society in regions where traditional norms have persisted for generations. Our findings underscore the importance of continuing efforts to expand access to labor market skills, not only for their economic benefits but also for their potential to catalyze social change and challenge deeply ingrained gender inequalities.

Table 1: Impact on economic outcomes and gender norms

	Mafita	N
<i>Primary</i>		
Income and employment	0.241 (0.046)*** [0.001]***	1706
Gender norms index (youth)	0.120 (0.043)*** [0.018]**	1706
Gender norms index (caregivers)	0.163 (0.073)** [0.048]**	792
<i>Secondary</i>		
Assets and expenditures	0.177 (0.047)***	1706
Job search behaviour	0.084 (0.048)*	1706

Notes: This table reports estimated effects of assignment to treatment (ITT). All outcome variables are mean effect indices, standardized using the control group mean and standard deviation. Each row presents results from a separate regression. All regressions control for individual characteristics at the time of randomization (age, gender, ethnicity, religion, and type of vulnerable group) and strata fixed effects, except for the . Demographics include . For the caregiver sample, we control for strata fixed effects. Robust standard errors are in parentheses. Multiple inference-adjusted p-values are in brackets. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 2: Examining effects on the gender norms of youth

	Mafita
Gender norms index (youth)	0.120 (0.043)***
<i>Components of index</i>	
Household decision-making	0.120 (0.043)***
Role in society	0.101 (0.043)**
Domestic violence	0.011 (0.047)
Number of youth	1706

Notes: This table reports estimated effects of assignment to treatment (ITT). Each row presents results from a separate regression. The outcome variable in the top panel is a mean effect index, standardized using the control group mean and standard deviation. We control for strata fixed effects and demographics at randomization. Demographics include age, gender, ethnicity, religion, and type of vulnerable group. Robust standard errors are in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 3: Heterogeneous effects by gender of participant

	Mafita
<i>Male</i>	
Income and employment	0.236*** (0.067)
Gender norms index (youth)	0.083 (0.065)
Number of youth	858
<i>Female</i>	
Income and employment	0.251*** (0.067)
Gender norms index (youth)	0.137** (0.064)
Number of youth	843

Notes: This table reports estimated effects of assignment to treatment (ITT), separately for males in the first panel and females in the second panel. Each row presents results from a separate regression. All outcome variables are mean effect indices, standardized using the control group mean and standard deviation. All regressions control for strata fixed effects and demographics at the time of randomization (age, gender, ethnicity, religion, and type of vulnerable group). Robust standard errors are in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 4: Impact on caregiver gender norms

	Mafita
Gender norms index (caregivers)	0.163** (0.073)
<i>Components of index</i>	
Female work decisions	0.122* (0.072)
Marriage and fertility	-0.013 (0.064)
Role in society	0.160** (0.071)
Household decision-making	0.021 (0.073)
Number of caregivers	792

Notes: This table reports estimated effects of assignment to treatment (ITT). Each row presents results from a separate regression. The outcome variable in the top panel is a mean effect index, standardized using the control group mean and standard deviation. All regressions control for strata fixed effects. Robust standard errors are in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 5: Impact on social networks

	Control Mean	Mafita
Social network index	-	0.201
	-	(0.048)***
<i>Components of index</i>		
Employed friends	2.816	0.273

Donation	0.601 (3.063) [0.568]
<i>Secondary</i>	
Trust in other religions	0.146 (0.046)***
Religiosity	-0.085 (0.046)*
Well-being	0.114 (0.049)**
Self-esteem	-0.032 (0.048)
Attitudes toward political violence	-0.004 (0.049)
Literacy	0.027 (0.047)
Number of youth	1706

Notes: This table reports estimated effects of assignment to treatment (ITT). All outcome variables are mean effect indices, standardized using the control group mean and standard deviation. For the youth sample, we control for strata fixed effects and demographics at randomization. Demographics include age, gender, ethnicity, religion, and type of vulnerable group. For the caregiver sample, we control for strata fixed effects. Robust standard errors are in parentheses. Multiple inference-adjusted p-values are in brackets. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A4: Balance on covariates for respondents

	Control	Treatment	p-value
<i>Randomization</i>			
Age	19.0	18.9	0.42
Almajiri (%)	24.1	25.4	0.54
IQE (%)	22.3	24.7	0.25
Orphans/vulnerable children (%)	26.9	24.8	0.32
Early school leavers (%)	21.7	21.0	0.70
Person with disabilities (%)	5.0	4.2	0.45
<i>Baseline</i>			
Female (%)	44.2	42.4	0.46
Age	16.6	16.3	0.47
Hausa (%)	70.0	68.3	0.45
Muslim (%)	72.0	71.6	0.85
Hours studying religious texts per day	3.0	3.1	0.49
Taught trade (%)	14.0	15.4	0.44
Attended skills training (%)	11.2	10.1	0.47
Currently working (%)	10.5	9.5	0.51
Looking for work (%)	53.7	54.1	0.86
Currently an apprentice (%)	7.1	6.4	0.58
	847	859	

Notes: This table reports sample means of demographics at the pre-randomization intake survey and at baseline, for the control and treatment groups. The last column reports p-values from a test of equality of means. The sample includes participants who took the survey at endline.

Table A5: Balance on covariates for attriters

	Control	Treatment	p-value
<i>Randomization</i>			
Age	19.2	19.7	0.32
Almajiri (%)	18.9	39.0	0.02
IQE (%)	16.2	4.9	0.08
Orphans/vulnerable children (%)	28.4	22.0	0.46
Early school leavers (%)	31.1	26.8	0.64
Person with disabilities (%)	5.4	7.3	0.68
<i>Baseline</i>			
Female (%)	59.3	23.1	0.00
Age	18.9	20.3	0.02
Hausa (%)	65.4	84.0	0.09
Muslim (%)	63.0	80.8	0.11
Hours studying religious texts per day	3.5	4.6	0.14
Taught trade (%)	9.3	26.9	0.04
Attended skills training (%)	20.4	19.2	0.91
Currently working (%)	5.6	17.4	0.10
Looking for work (%)	71.7	68.0	0.74
Currently an apprentice (%)	6.1	4.5	0.79
	77	41	

Notes: This table reports sample means of demographics at the pre-randomization intake survey and at baseline. The last column reports p-values from a test of equality of means. The sample includes participants who did not take the survey at endline.

Table A6: Attrition rates

	Control	Treatment	p-value
Attrition rate (%)	8.0	4.6	0.00
Attrition rate - southern Kaduna (%)	8.9	3.1	0.00
Attrition rate - other centers (%)	7.4	5.6	0.21

Notes: This table reports attrition rates across treatment and control groups and p-values from a test of equality of means.

Table A7: Balance on covariates for attriters - excluding southern Kaduna centers

	Control	Treatment	p-value
<i>Randomization</i>			
Age	18.6	19.4	0.18
Almajiri (%)	31.7	46.7	0.21
IQE (%)	14.6	6.7	0.30
Orphans/vulnerable children (%)	19.5	20.0	0.96
Early school leavers (%)	34.1	20.0	0.20
Person with disabilities (%)	0.0	6.7	0.10
<i>Baseline</i>			
Female (%)	60.0	11.1	0.00
Age	18.0	20.3	0.01
Hausa (%)	96.0	100.0	0.42
Muslim (%)	96.0	100.0	0.40
Hours studying religious texts per day	5.0	5.8	0.31
Taught trade (%)	4.0	33.3	0.01
Attended skills training (%)	20.0	22.2	0.86
Currently working (%)	12.0	25.0	0.29
Looking for work (%)	79.2	66.7	0.37
Currently an apprentice (%)	4.2	6.7	0.74
	44	30	

Notes: This table reports sample means of demographics at the pre-randomization intake survey and at baseline, for the control and treatment groups in all training centers except the two in Southern Kaduna. The last column reports p-values from a test of equality of means. The sample includes participants who took the survey at endline.

Table A8: Impact on economic outcomes and gender norms - excluding the centers in southern Kaduna

	Mafita	N
<i>Primary</i>		
Income and employment	0.227 (0.056)*** [0.001]***	1019
Gender norms index (youth)	0.122 (0.055)** [0.093]*	1019
Gender norms index (caregivers)	0.156 (0.106) [0.197]	409
<i>Secondary</i>		
Assets and expenditures	0.123 (0.062)**	1019
Job search behaviour	0.028 (0.057)	1019

Notes: This table reports estimated effects of assignment to treatment (ITT) on respondents in all training centers except the two in Southern Kaduna. All outcome variables are mean effect indices, standardized using the control group mean and standard deviation. For the youth sample, we control for strata fixed effects and demographics at randomization. Demographics include age, gender, ethnicity, religion, and type of vulnerable group. For the caregiver sample, we control for strata fixed effects. Robust standard errors are in parentheses. Multiple inference-adjusted p-values are in brackets. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table reports estimated effects of assignment to treatment (ITT). The outcome variable in the top panel is a mean effect index, standardized using the control group mean and standard deviation. We control for strata fixed effects and demographics at randomization. Demographics include age, gender, ethnicity, religion, and type of vulnerable group. We also add demographics at baseline, which include time spent of religious activities, time spent at work, marital status, and whether the individual was taught any trade. Standard deviations of the control group are in parentheses, below the control means. Robust standard errors are in parentheses, below the ITT estimates. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A13: Impact on expanded gender norms index (female youth)

	Mafita	N
idx_fwoman_m	0.154** (0.061)	843
<i>Components of index</i>		
Marriage and fertility	0.047 (0.060)	843
Household decision-making	0.175*** (0.062)	843
Role in society	0.131** (0.064)	843
Domestic violence	-0.037 (0.068)	843
Raven's matrix	0.064 (0.070)	843

Notes: This table reports estimated effects of assignment to treatment (ITT). The outcome variable in the top panel is a mean effect index, standardized using the control group mean and standard deviation. We control for strata fixed effects and demographics at randomization. Demographics include age, ethnicity, religion, and type of vulnerable group. Robust standard errors are in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A14: Impact on caregiver gender norms index: Including caregivers with multiple wards

	Mafita
Gender norms index (caregivers)	0.123* (0.068)
<i>Components of index</i>	
Female work decisions	0.062 (0.067)
Marriage and fertility	-0.007 (0.061)
Role in society	0.146** (0.065)
Household decision-making	0.027 (0.066)
Number of caregivers	903

Notes: This table reports estimated effects of assignment to treatment (ITT). The outcome variable in the top panel is a mean effect index, standardized using the control group mean and standard deviation. We control for strata fixed effects. Robust standard errors are in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A15: Impact on components of caregiver gender norms index

	Mean	Std dev	Mafita
<i>Female work decisions</i>			
14y female single working at home	0.73	0.45	0.036 (0.027)
14y female single working outside home	0.40	0.49	0.043 (0.033)
18y female single working at home	0.96	0.21	0.019 (0.015)
